# **All Relevant Feature Selection**

### Racapping Our Path So Far

### We started with a somewhat clear goal

- Given data containing candidate correlates and a discrete target
- ...We aimed at identifying the most relevant correlates

### We applied a baseline approach (Lasso) to:

- Obtain a surrogate for our data-generation process
- Analyze the impact of each candidate correlate (feature)
- Identify the most relevant correlates

### Our baseline turned out to be largely insufficient, so we:

- Trained a non-linear model to obtain a more reliable surrogate
- Learn to assess importance via a permutation-based method
- Learned to explain individual examples via SHAP

We still have a couple of major open problems...

### **Open Problems**

### There's a mistmatch between local and global explanations

- We are using SHAP to assess local feature effects
- ...And permutation importance for global feature effects

As a side effect, there may be inconsistences in our analysis

### We still don't know how to identify the most relevant features

- Like in the Lasso appproach we could think of using a threshold
- ...But we still don't know how such threshold should be calibrated

#### It's time that we fix both of them

### Global Feature Analysis via SHAP

### SHAP explanations can be aggreated to get global importance scores

By default, this is done by averaring absolute SHAP values:

$$\bar{\phi}_j(x) = \frac{1}{n} \sum_{i=1}^m |\phi_j(x_i)|$$

Other aggregation functions can also be used (e.g. max)

#### By using aggregated SHAP scores

...We ensure that our local and global analysis have a similar semantic

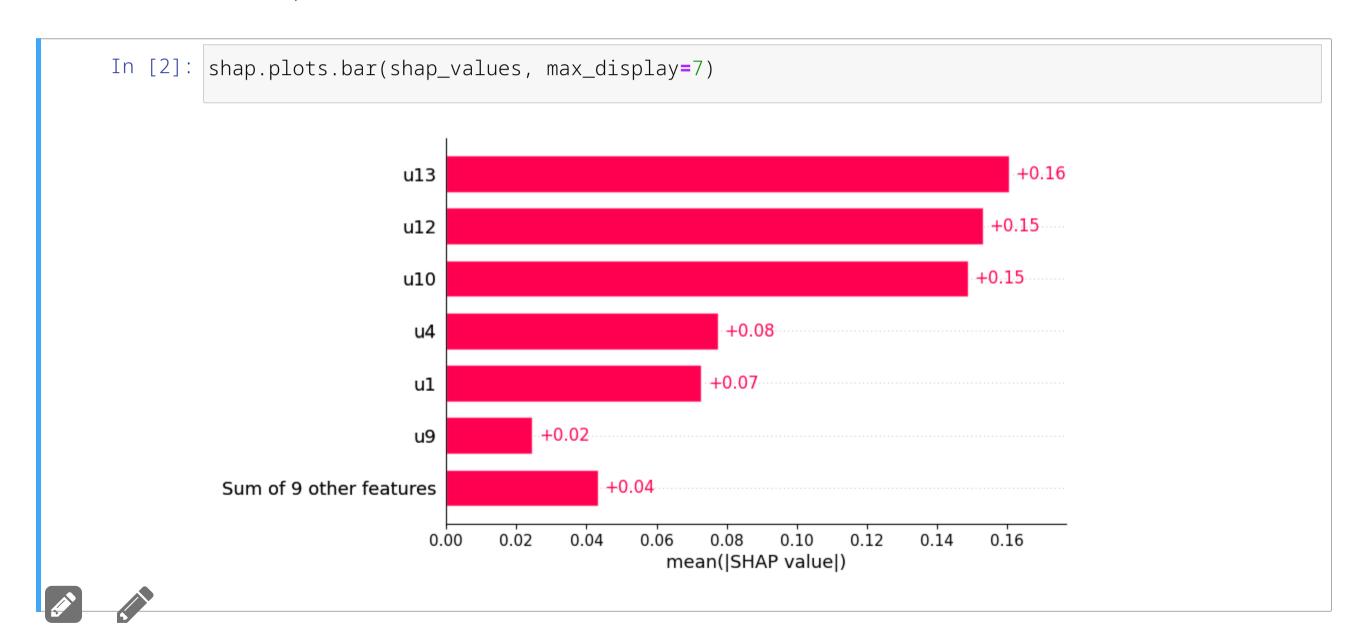

- Permutation Importance are a perfectly viable approach
- ...And sometimes may be more appropriate than SHAP

However, when doing a rigorous analysis consistency is important

### Global Feature Analysis via SHAP

### The SHAP library provide convenience functions to plot aggregated values

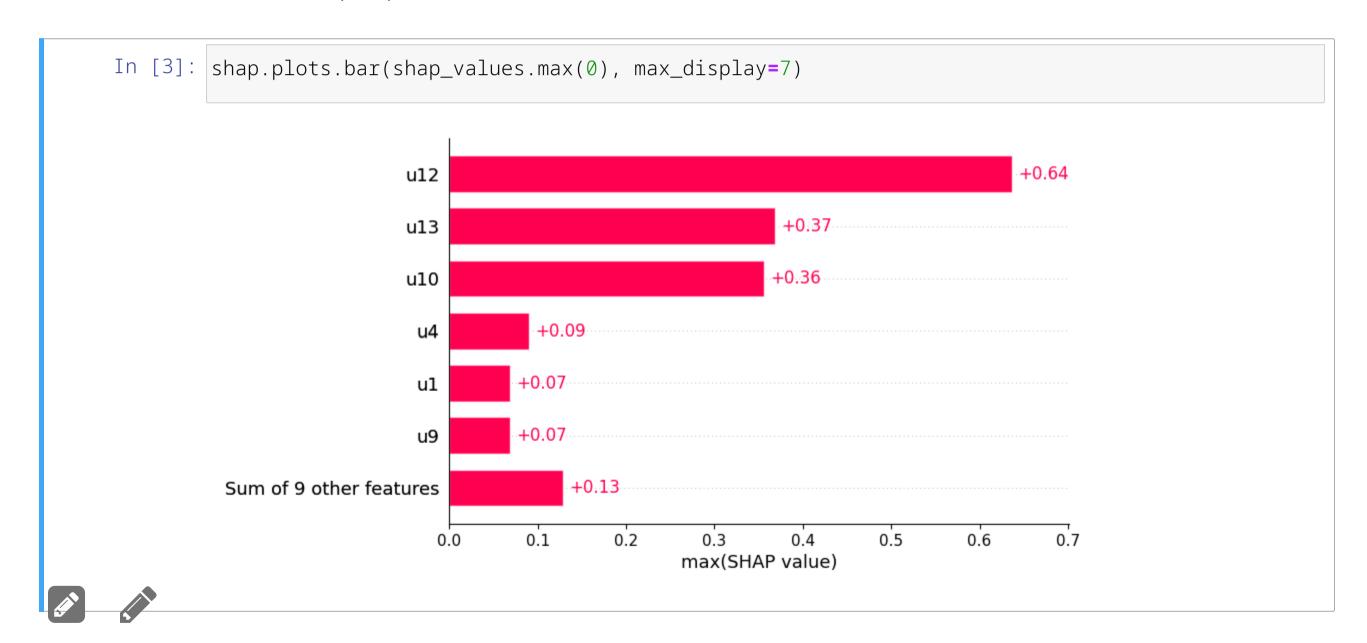

Here's how to plot mean (absolute) SHAP values:

### Global Feature Analysis via SHAP

### The SHAP library provide convenience functions to aggregated values

Here's how to display the maximum (absolute) SHAP values:

### A viable approach for feature selection consists in solving:

$$\underset{S \subseteq \mathcal{X}}{\operatorname{argmin}} \left\{ |\mathcal{S}| : \hat{y} = \hat{f}_{\mathcal{S}}(x_{\mathcal{S}}), L(y, \hat{y}) \leq \theta \right\}$$

Where x, y denote all the training data. Intuitively:

- lacksquare We search for the smallest subset of features  ${\cal S}$
- lacksquare ...Such that a model  $\hat{f}_{\mathcal{S}}$  trained over only over them
- ...Still has an acceptable (cross-validation) accuracy

Heuristics (e.g. greedy search) can be used to improve scalability

### A viable approach for feature selection consists in solving:

$$\underset{S \subseteq \mathcal{X}}{\operatorname{argmin}} \left\{ |\mathcal{S}| : \hat{y} = \hat{f}_{\mathcal{S}}(x_{\mathcal{S}}), L(y, \hat{y}) \leq \theta \right\}$$

Where x, y denote all the training data. Intuitively:

- lacksquare We search for the smallest subset of features  ${\cal S}$
- lacksquare ...Such that a model  $\hat{f}_{\mathcal{S}}$  trained over only over them
- ...Still has an acceptable (cross-validation) accuracy

Heuristics (e.g. greedy search) can be used to improve scalability

### This optimization-driven approach

- ...Can be customized by adjusting the constraint and cost function
- 2 . 2 an reduce data storage and location costs on the deployed model

If we care just about cost and accuracy, the optimization approach is perfect

But it is not suitable for our current case study... Can you tell why?

If we care just about cost and accuracy, the optimization approach is perfect

But it is not suitable for our current case study... Can you tell why?

#### For a number of reasons:

- We care about finding all the relevant features, not a minimal set
- How should the accuracy threshold be calibrated?
- What about the noise induced by retraining?

If we care just about cost and accuracy, the optimization approach is perfect

But it is not suitable for our current case study... Can you tell why?

#### For a number of reasons:

- We care about finding all the relevant features, not a minimal set
- How should the accuracy threshold be calibrated?
- What about the noise induced by retraining?

If we wish to use ML for data analysis, we need another approach

...In particular, we will rely on statistical hypothesis testing (HT)

### Statistical Hypothesis Testing

#### HT is one of the main mathematical workhorses of scientific research

HT builds evidence for a hypothesis by refuting a competing one:

- lacksquare We start from a hypothesis  $oldsymbol{H}$  and some data  $oldsymbol{x}$
- lacktriangle We formulate a competing null hypothesis  $H_0$
- lacktriangle We define a test statistic T(X), monotonically related to H
- lacksquare We define the theoretical probability of T(X) under  $H_0$ , i.e.  $P(T(X) \mid H_0)$
- lacksquare We compute the its empirical value for our data  $t=P(T(x)\mid H_0)$
- lacksquare We compute the probability that T(X) is as extreme as t under  $H_0$ , i.e.:

$$p = P(T(X) \ge t \mid H_0)$$

■ If  $p \leq 1 - \alpha$  for some confidence  $\alpha$ , we reject the null hypothesis

This is probably very confusing...

# Let's make an example for our case

### Hypothesis, Data, and Null-Hypothesis

### First, we need to define our hypothesis and data

We care about identifying correlates, so a possible choice might be:

- $\blacksquare H \equiv "r(X,Y) \ge r^*"$ , for some correlation measure r
- $data \equiv "x, y"$ , i.e. our sample

### Hypothesis, Data, and Null-Hypothesis

### First, we need to define our hypothesis and data

We care about identifying correlates, so a possible choice might be:

- $\blacksquare H \equiv "r(X,Y) \ge r^*"$ , for some correlation measure r
- $data \equiv "x, y"$ , i.e. our sample

### Now we need a competing null hypothesis

A good choice might be  $H_0 \equiv$  "the observed result is due to chance"

- In most cases, the null hypothesis assumes what we observe is due to chance
- lacksquare If we manage to reject it, we can claim that H is more likely true
- lacktriangle The tricky part is choosing a  $H_0$  for which we can compute probabilities
- ...Without introducing unnecessary assumptions

Now we need some "test" related to  ${\cal H}$  and  ${\cal H}_0$  ...And it must be something for which we can compute probabilities

## How do we do that?

### **Test Statistic and Theoretical Probability**

Let's consider the event " $r(X, Y) \ge r^*$ "

Since it has a binary outcome, it will follow a <u>Bernoulli distribution</u>

- If we assume that the correlation is due to chance...
- lacksquare ...Then the associated probability should be  $^1/_2$

### Let's pretend we make repeated experiments

The number of observed events T(X,Y) will follow a binomial distribution

- $\blacksquare$  Given the number of experiments n
- ...The probability of T(X,Y) should be  $P(T\mid H_0)=B(n,{}^1/_2)$

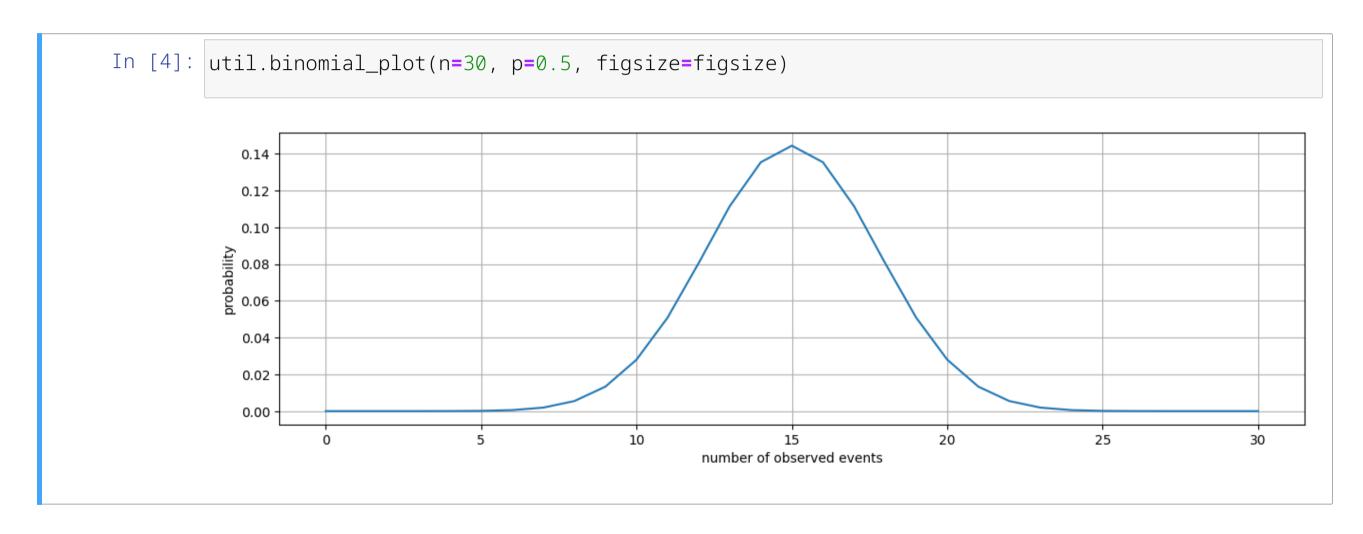

T is our test statistics, B(n, 1/2) its theoretical distribution under  $H_0$ 

### **Theoretical Probability Computation**

### We can easily compute and plot the distribution

- This tells us how likely we are to observe a certain number of events
- ...Assuming that the null hypothesis is true

# What about the empirical probability?

We need to simulate lack of correlation ...Without additional assumptions

### **Empirical Probability Computation**

### We can use a Monte-Carlo approach

The trick is once again relying on permutations

- lacksquare If we shuffle the values of one variable (say the values x of X)
- lacktriangleright ...We can get a correlation with  $oldsymbol{Y}$  only by chance
- ...But we otherwise preserve the distribution of the sample

### **Empirical Probability Computation**

### We can use a Monte-Carlo approach

The trick is once again relying on permutations

- lacktriangle If we shuffle the values of one variable (say the values x of X)
- lacksquare ...We can get a correlation with  $oldsymbol{Y}$  only by chance
- ...But we otherwise preserve the distribution of the sample

### We can mitigate sampling noise via repeated experiments

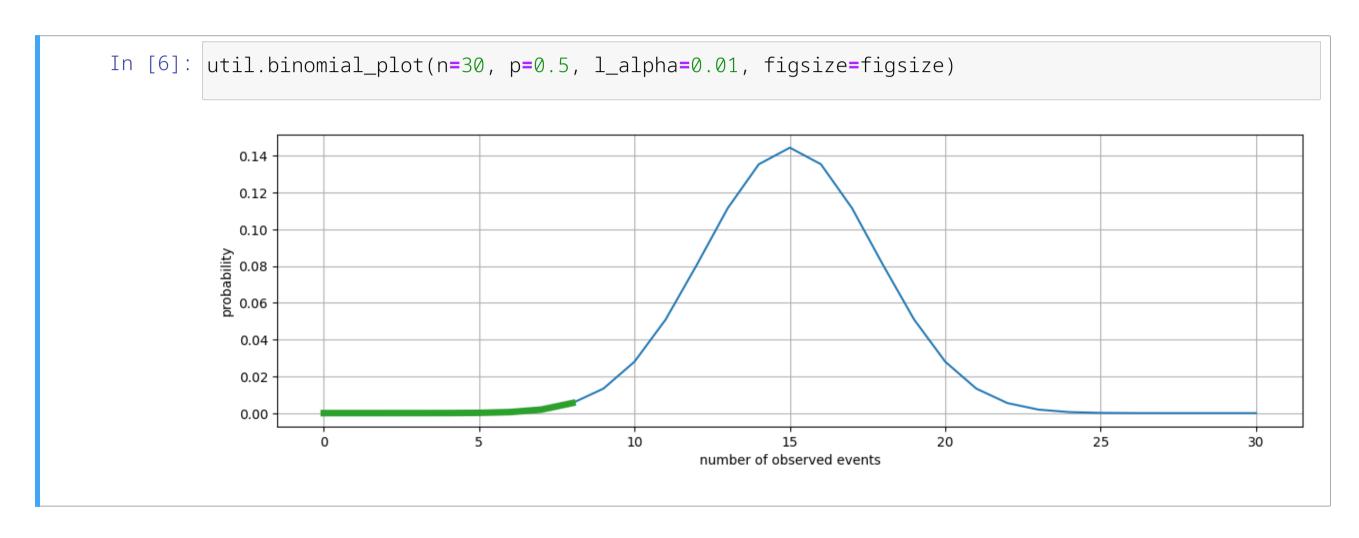

- Then, we take our empirically observed number of events t = T(x, y)
- ...And we match it against the theoretical probability
- We care about the probability that  $T(X,Y) \ge t$
- $\blacksquare$  ...Since any value larger than t would still support the null-hypothesis

### p-Value and the Statistical Test

### Basically, there is a "target interval" in the distribution

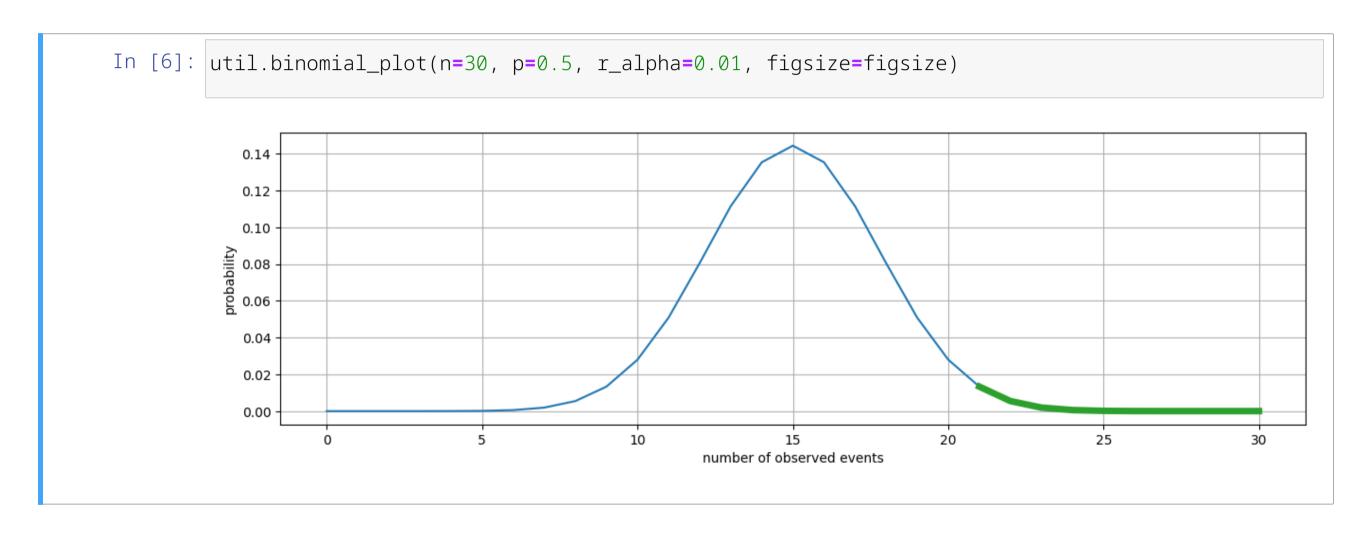

- For any value t in the interval, we have  $P(T(X,Y) \ge t \mid H_0) \le 1 \alpha$
- lacktriangleright ...Where lpha is our desired confidence level

### p-Value and the Statistical Test

### Basically, there is a "target interval" in the distribution

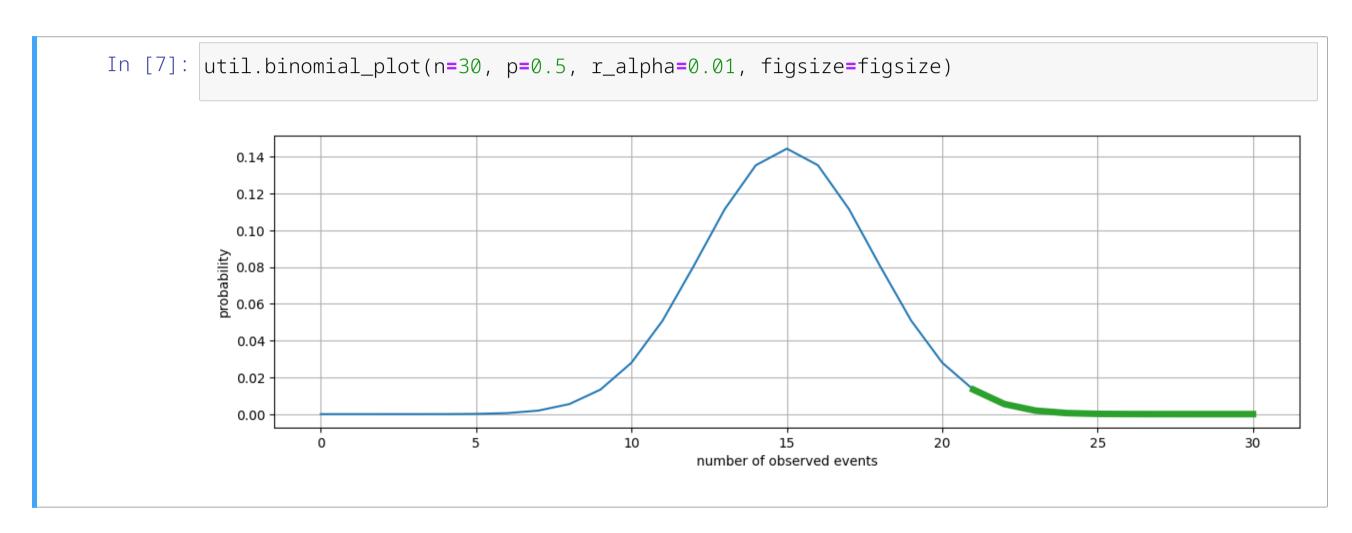

- lacktriangle We still need a threshold (i.e. lpha) to define the interval
- ...But it's a probability, so it's easier to define (usually  $\alpha=0.01$  or  $\alpha=0.05$ )

### p-Value and the Statistical Test

### Basically, there is a "target interval" in the distribution

- In practice it's more common to compute the p-value  $P(T(X,Y) \ge t \mid H_0)$
- lacksquare ...Which can then be immediately compared with 1-lpha

### **Back to the Procedure Description**

### The procedure should be clearer now

Let's recap the steps:

- lacksquare We start from a hypothesis  $oldsymbol{H}$  and some data  $oldsymbol{x}$
- lacksquare We formulate a competing null hypothesis  $H_0$
- lacktriangle We define a test statistic T(X), monotonically related to H
- lacksquare We define the theoretical probability of T(X) under  $H_0$ , i.e.  $P(T(X) \mid H_0)$
- lacksquare We compute the its empirical value for our data  $t=P(T(x)\mid H_0)$
- lacksquare We compute the probability that T(X) is as extreme as t under  $H_0$ , i.e.:

$$p = P(T(X) \ge t \mid H_0)$$

■ If  $p \leq 1 - \alpha$  for some confidence  $\alpha$ , we reject the null hypothesis

### Testing a Hypothesis and Its Negation

### In our case, the method works also for testing the opposite hypothesis

- Our hypothesis becomes  $\neg H \equiv "r(X,Y) < r^*"$
- The null hypothesis is the same as before
- The test statistics is just n T(X, Y), for the same T as before

Then we can proceed as in the previous case

### Testing a Hypothesis and Its Negation

### In our case, the method works also for testing the opposite hypothesis

- Our hypothesis becomes  $\neg H \equiv "r(X,Y) < r^*"$
- The null hypothesis is the same as before
- The test statistics is just n T(X, Y), for the same T as before

Then we can proceed as in the previous case

#### Since we are relying on the same test statistics

...We can use the same set of experiments to test both hypotheses

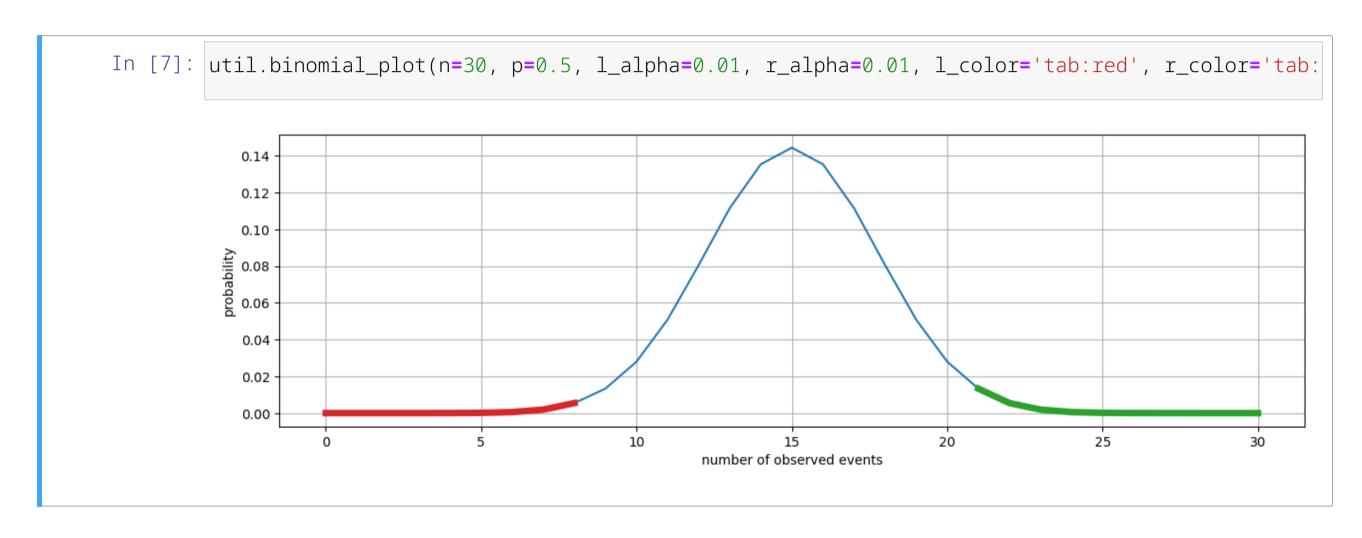

- Intuitively, in both cases we look at the number of events T(xy)
- lacksquare If T(x,y) is sufficiently high, it's likely that the H holds
- ...If T(x, y) is sufficiently low, it's likely that  $\neg H$  holds

### Testing a Hypothesis and Its Negation

In other words, we will end up having two target intervals

- $\blacksquare$  If T(x, y) lands in the green region, we support H (e.g. strong correlation)
- If T(x, y) lands in the red region, we support  $\neg H$  (e.g. weak correlation)
- If T(x,y) lands in the center region, we support no claim

#### **Boruta**

### The approach we have just seen is the backbone of the Boruta algorithm

- The Boruta algorithm is a SotA feature selection method
- ...That relies in statistical HT to determine relevant features

### Like in our analysis, the method relies on surrogate models

...And in particular on tree ensembles (the name refers to a Slavic forest spirit)

- As a consequence, the algorithm can deal with non-linear correlations
- ...And accounts for interactions between multiple features

#### Boruta is an all-relevant feature selector

- This makes it particularly well suited for scientific analyses
- ...But it can be used to reduce data collection costs or improve generalization

### **Tested Hypothesis in Boruta**

### Boruta relies on a measure of feature importance

- The original algorithm and the <u>BorutaPy package</u> use permutation importance
- The more recent <u>BorutaShap package</u> relies on average SHAP values In both cases, importance is computed w.r.t. a reference dataset

### The hypothesis H being tested is more general than ours and consists in:

"Feature j is important among those in the dataset, according to the chosen metric"

- This is much more general than the one we considered
- ...And it require as slighly more sophisticated test statistics

### **Test Statistics in Boruta**

### The main idea is stil to rely on permuted features

Let (x, y) be our original dataset

- lacksquare First, we augmented it by introducing permuted versions  $oldsymbol{\mathcal{X}}$  of all features
- These are called shadow features by the algorithm. Let their values be  $\tilde{x}$  Then, we train a predictive model on  $(x, \tilde{x}, y)$

### Let $\phi_i(x, \tilde{x}, y)$ be the importance of feature j, on the augmented dataset

- lacksquare If the feature is important, its  $oldsymbol{\phi}_j$  should beat the shadow features
- Therefore, we can consider the event

$$\phi_j((x, \tilde{x}), y) > \max_{j \in \tilde{\mathcal{X}}} \phi_j((x, \tilde{x}), y)$$

#### **Test Statistics in Boruta**

### Then the testing statistics T is similar to the one we used:

- The algorithms performs multiple experiments (retraining the model)
- ...And counts the number of times the event is satisfied ("hits")

### The thereotical distribution for T under $H_0$ is mostly a binomial

- The algorithm needs to apply some statistical corrections
- $\blacksquare$  ...Since we are testing multiple features together (we have a  $\max$ )

### Boruta tests both the positive and negative hypothesis

Therefore, at the end of the process:

- Some features will be confirmed important
- Some features will be confirmed unimportant
- me features will be remain tentative

### **Using Boruta in Practice**

### We'll use Boruta through the BorutaShap package

```
In [8]: bfs = BorutaShap(importance_measure='shap', classification=True)
bfs.fit(X=X, y=y, n_trials=100, sample=False, train_or_test='test', normalize=True, verbose=

A Jupyter widget could not be displayed because the widget state could not be found. This could happen if the kernel
storing the widget is no longer available, or if the widget state was not saved in the notebook. You may be able to
create the widget by running the appropriate cells.

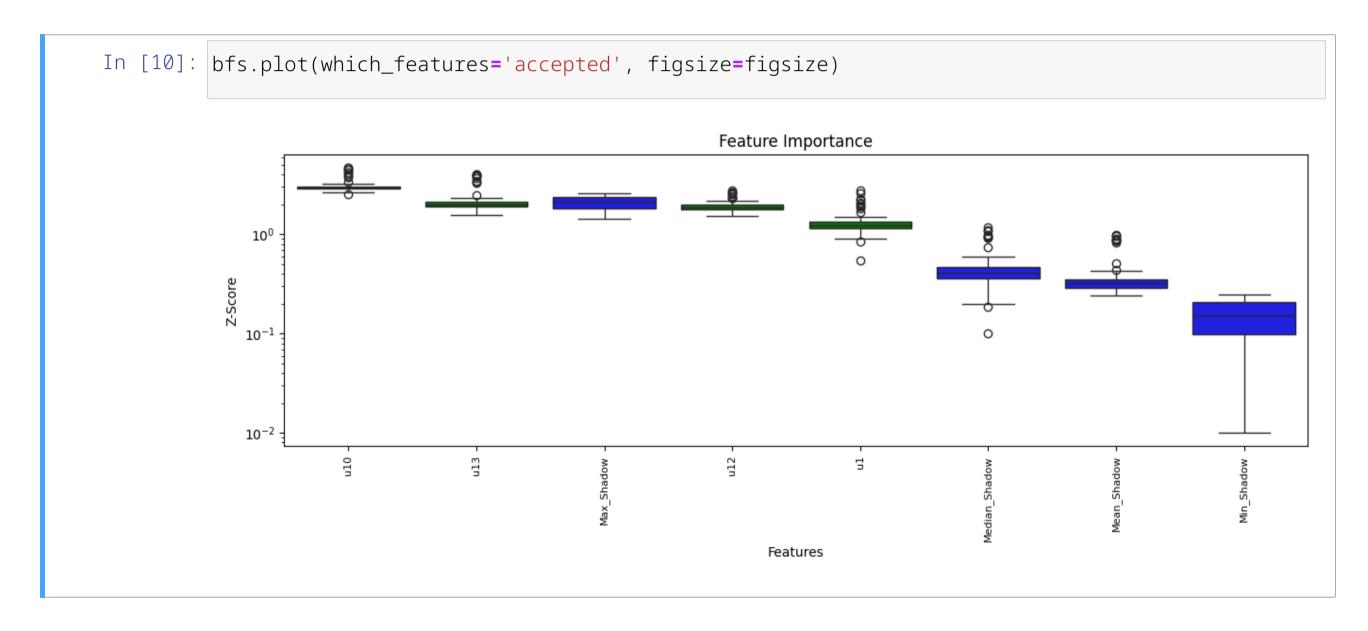

4 attributes confirmed important: ['u10', 'u12', 'u13', 'u1']
11 attributes confirmed unimportant: ['u14', 'u5', 'u7', 'u8', 'u11', 'u3', 'u0', 'u4', 'u
6', 'u9', 'u2']
0 tentative attributes remains: []
```

- We can choose to use either the testing or training importance
- The algorithm also determines the best number of estimators
- The algorithm allows the use of a clever sampling procedure
- ...To reduce the number of averaged SHAP values (and therefore the run-time)

**Warning:** as of Nov 2023, the PyPI version of BorutaShap is not compatible with the most recent scikit-learn release (this lecture uses the GitHub version)

### **Using Boruta in Practice**

## We can plot the the $\phi_j$ distribution for the confirmed important features

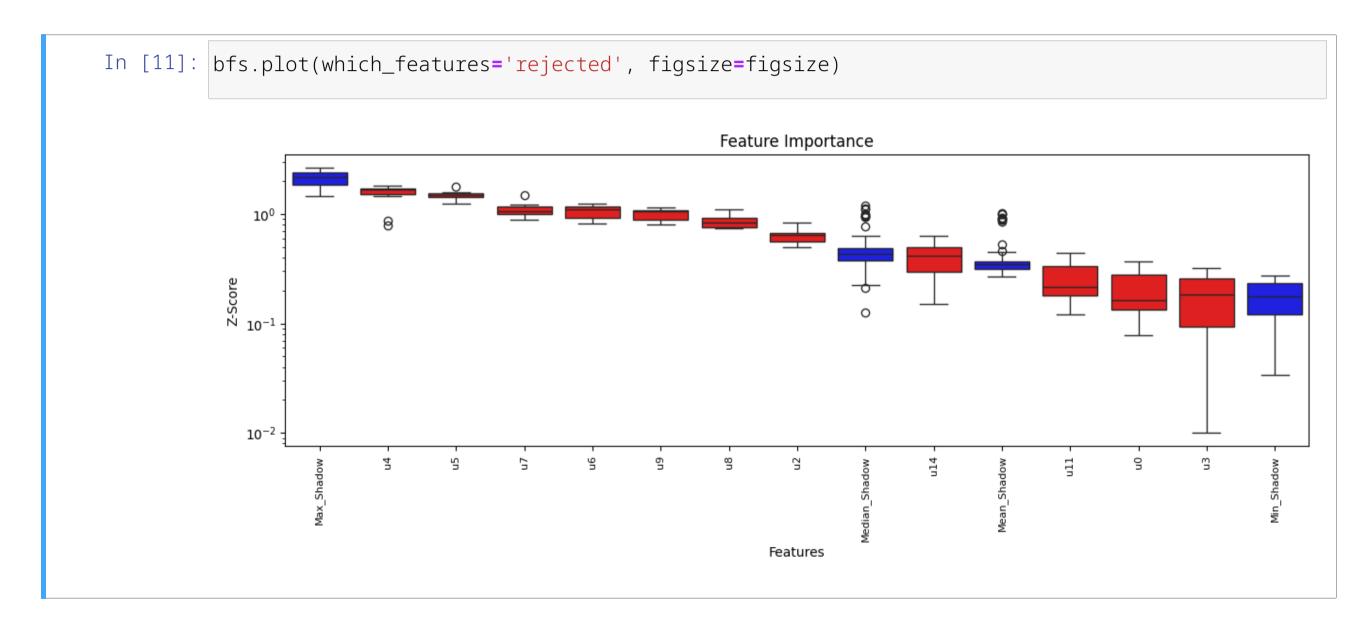

Stribution data for the shadow features is shown for comparison

### **Using Boruta in Practice**

### We can to the same for the confirmed unimportant features

Ok, but... Did it work?

### What we Have Discovered

### So far, by using Boruta we found that:

lacksquare There seem to be 4 relevant features, i.e.  $U_1, U_{10}, U_{12}, U_{13}$ 

### By inspecting the data we found that:

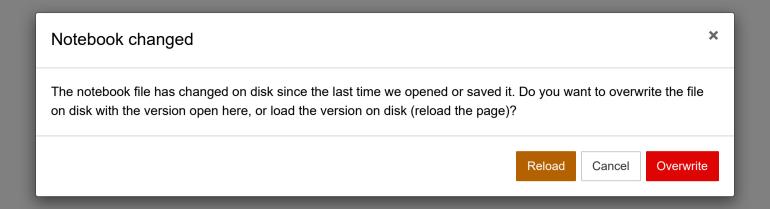

- lacksquare  $U_{12}$  and  $U_{13}$  are roughly Normally distributed
- lacksquare  $U_1$  is not Normally distributed
- $U_{10}$  is binary

### By using SHAP we found that:

- lacksquare  $U_{13}$  has a mostly monotonic effect
- lacksquare  $U_{12}$  has a complex effect, which seems to be modulated by  $U_{10}$
- lacksquare  $U_1$  seems to have mostly an anti-monotonic effect

# We can now inspect the ground truth process

So we can check whether our results actually hold

The ground-tru

- ...And also as tools for a scientific analysis!

### Explainability is an important topic in Al

- It is one of the main approaches to make an AI model transparent
- This critical when AI systems need to interact with human users
- ...And for some domains it is also required by existing regulations

#### Beware of correlated features

- Strongly correlated features (e.g mediated-mediator) may mislead algorithms
- Dealing with those is still a partially open problem!
